

τ neutrino detection

Saurabh Sandilya
DHEP-TIFR
11th May, 2010

Outline

- Standard Model and History
- Detection of neutrinos (specifically ν_τ)
- **Direct Observation of NU Tau (DONUT)**
- **Oscillation Project with Emulsion-tRacking Apparatus (OPERA)**

The Standard Model of Particle Physics

Three Generations of Matter (Fermions)

	I	II	III	
mass →	2.4 MeV	1.27 GeV	171.2 GeV	0
charge →	$\frac{2}{3}$	$\frac{2}{3}$	$\frac{2}{3}$	0
spin →	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1
name →	u up	c charm	t top	γ photon
	4.8 MeV	104 MeV	4.2 GeV	0
	$-\frac{1}{3}$	$-\frac{1}{3}$	$-\frac{1}{3}$	0
	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1
Quarks	d down	s strange	b bottom	g gluon
	<2.2 eV	<0.17 MeV	<15.5 MeV	91.2 GeV
	0	0	0	0
	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1
	ν_e electron neutrino	ν_μ muon neutrino	ν_τ tau neutrino	Z⁰ weak force
	0.511 MeV	105.7 MeV	1.777 GeV	80.4 GeV
	-1	-1	-1	±1
	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1
Leptons	e electron	μ muon	τ tau	W[±] weak force

Bosons (Forces)

1898- electron

1937-muon

1956-electron neutrino

1962-muon neutrino

1974-charm quark

1975-tau lepton

1977-bottom quark

1995-top quark

2000-tau neutrino

Tau Neutrino was the last standard model fermion to be directly observed.

Discovery of electron neutrino: 1956

The million-dollar particle

- Reactor neutrinos: $\bar{\nu}_e + p \rightarrow n + e^+$
- $e^+ + e^- \rightarrow \gamma + \gamma$ (0.5 MeV each)
- $n + {}^{108}\text{Cd} \rightarrow {}^{109}\text{Cd}^* \rightarrow {}^{109}\text{Cd} + \gamma$ (delayed)

Reines-Cowan: Nobel prize 1995

History

Discoveries of ν_μ and ν_τ

Muon neutrino: an unexpected discovery (1962)

- Neutrinos from pion decay: $\pi^- \rightarrow \mu^- + \bar{\nu}_{(\mu)}$
- $\bar{\nu}_{(\mu)} + N \rightarrow N' + \mu^+$
- Always a muon, never an electron/positron

Steinberger-Schwartz-Lederman: Nobel prize 1988

Tau neutrino: expected, but hard to identify (2000)

DONUT experiment at Fermilab: $\nu_\tau + N \rightarrow \tau + N'$

Evidences before discovery

- The Discovery of τ in 1975 along with the proof in 1962 that ν_μ was distinguished from the ν_e , implied the existence of unique τ neutrino
- Constraint on total number of neutrinos (to be 3) by Big Bang nucleosynthesis
- Precise measurement of partial decay width of Z at LEP, predicts 3 light neutrinos

Neutrino interactions

- Neutrino interactions can be reduced to two categories :
 1. Neutral Current (Z)
 2. Charged Current(+/-W)
- The purpose of the DONuT experiment is to study CC events

$$\nu_{\tau} + \mathbf{N} \rightarrow \tau^{-} + \mathbf{X}$$

$$\bar{\nu}_{\tau} + \mathbf{N} \rightarrow \tau^{+} + \mathbf{X}$$

- However during data taking DONuT was recording interactions of all flavors of neutrinos.

1. CC event $\nu_l + \mathbf{N} \rightarrow l^{-} + \mathbf{X}$

2. NC event $\nu_l + \mathbf{N} \rightarrow \nu_l + \mathbf{X}$

- Background: Charm production in NC event of ν_{μ} and ν_e

$$\nu_l + \mathbf{N} \rightarrow l^{-} + C^{\pm} + \mathbf{X}$$

Neutrino Interactions

ν_μ CC \rightarrow penetrating
muon \rightarrow *long* event

CC ν_μ interaction to a muon, giving long track of muon.

ν_e CC \rightarrow showering
electron \rightarrow *short* event

CC ν_e interaction to an electron, producing showering event.

ν NC \rightarrow no muon,
hadrons \rightarrow *short* event

NC event any neutrino can undergo, only multiple hadron products

ν_τ CC \rightarrow 18% BF
to a penetrating
muon \rightarrow *long* event

ν_τ CC \rightarrow 18% BF
to an
electron \rightarrow *short*
event

CC ν_τ bit more difficult due to τ lifetime

DONuT Design

1. 800 GeV proton beam (Tevatron) stopped in beam dump (block of tungsten).
2. Produces D_s (meson) decays to ν_τ and τ
3. τ then decays to tau neutrino
4. Which is detected in emulsion target

Beam Dump

- 800 GeV proton beam from TeVatron collide with block of tungsten.
8 x 10¹² protons per 20 second spill
- In the Dump D_s (along with other charm particles) is produced .

- Neutrinos from decay of charmed particle are called prompt neutrinos.
- Neutrinos from decay of π^\pm and K^\pm are called Non prompt neutrinos.
- 95% of neutrino flux are ν_e (37%) and ν_μ (58%) and rest is ν_τ
- 93% of ν_e are prompt, substantial ν_μ are both prompt and non prompt and almost ν_τ all are prompt

Neutrino Beam Energy

- The calculated (PYTHIA output) neutrino energy spectra of all neutrinos that interacted in DONuT

**K. Kodama (DONuT
Collaboration), Physical
Review D 78, 052002
(2008)**

- The average neutrino energy was 53 GeV

DONuT Detector

DONUT Detector

DONuT Target

- DONuT scientists had to overcome two difficulties:
1. High resolution: τ has short lifetime $\sim 239 \cdot 10^{-15}$ s (PDG)
 2. tau-neutrino is extremely non-interacting

Solution: EMULSION

*Spatial Resolution $\sim 1 \mu\text{m}$

*Extremely sensitive and also continuously sensitive

*Target and detector are not separate.

*To improve target densities emulsions are layered on sheets of metal.

*number of grains developed per unit track length gives rate of energy loss

DONuT Target

DONUT Target Station

- Emulsion-Target
- $50 \times 50 \times 6 \text{ cm}^3$
- Aluminium support frame
- Masses of these module range from 56kg - 100kg

OPERA

- An appearance experiment to search for $\nu_\mu \leftrightarrow \nu_\tau$ oscillations in CNGS beam
- OPERA is a long baseline experiment located at the Gran Sasso laboratory.
- The Detector design is based on massive lead/nuclear emulsion target
- The Concept of emulsion detector in OPERA is same as DONuT, one difference in the nature of passive material. In OPERA there are lead plates but in DONuT there are iron plates
- The most stringent constraint comes from SuperK which yields the following 90% C.L.
 - $\Delta m^2 \sim (2-6) \times 10^{-3} \text{ eV}^2$
 - $\text{Sin}^2 2\theta \sim 0.8 - 1$

OPERA Requirements

- The energy of ν_μ must be over the τ production threshold.
- The distance from the ν_μ production point to the detector (baseline) must be long enough to allow a reasonable fraction of neutrinos to oscillate to a different flavour.
- The beam intensity must be high enough to provide a reasonable number of events.
- The detector must have enough mass to provide a reasonable number of events.
- The detector must have a capability to detect short-lived leptons, that is high spatial resolution.

Detecting nu tau @ OPERA

Conclusion

- The results from DONuT in July 2000, confirmed the existence of most suspected ν tau.
- Finding τ decay in DONuT was made possible by state-of-the-art digital technology with precise nuclear emulsion.
- The OPERA detector received CNGS ν beam for a brief period in 2006 and obtained first event in 2007.

THANK YOU !!!
