Algorithms for frustrated spin models

Kedar Damle, CCP2015, IIT Guwahati Tata Institute, Bombay

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Antiferromagnetism in Mott insulators:

 Antiferromagnetic exchange interactions of magnetic ions in insulators:

 $E = J \sum_{\langle ij \rangle} \mathbf{S}_i \cdot \mathbf{S}_j \quad J > 0$

- When is J>0, large? Difficult (quauntum chemistry) question, with thumb-rule answer: Goodenough-Kanamori-Anderson rules J.B. Goodenough, *Magnetism and the Chemical Bond (1963)* (exceptions known, *e.g.* Oles *et. al.* 2006)
- Sometimes possible to "measure" J: Inelastic neutron scattering in high field.

e.g. Yb₂Ti₂O₇ Ross et al. PRX 2011

Triangles on my mind: Frustration and spin liquid behaviour

+n

• Triangles \rightarrow *frustrated* antiferromagnetism

Competing interactions frustrate Neel order

- 'Quenching' of exchange allows new physics to take center-stage: Spin liquids
- Macroscopic degeneracy of *classical* minimum energy configurations.
- ► At intermediate T_f < T < JS², spin correlations reflect this macroscopic degeneracy:

No Bragg peaks in structure factor \rightarrow correlated liquid state

Frustration and entropic interactions

- Frustrated magnets: Large degeneracy of minimum energy configurations
- At T
 J: system samples minimally frustrated subspace (Or falls out of equilibrium...)

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Fluctuations generate entropic interactions

Order by disorder:

- Low temperature physics dominated by entropic interactions
- Characteristic signatures in structure factor
- More dramatic cases: Order-by-thermal/quantum disorder

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Sign problem in Quantum Monte Carlo

$$\blacktriangleright \ Z = \sum_{\mathcal{C}} W(\mathcal{C})$$

- In classical stat. mech. $W \propto \exp(-E/k_BT) > 0$
- For quantum systems $Z = \text{Tr}(e^{-H/k_BT})$ Berry phase effects: *W* need not be positive
 - \rightarrow Exponentially deteriorating error bars

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

Sign problem and frustration

• Hamiltonian written as sum over links: $H = \sum_{l} H_{l}$

►
$$Z = \text{Tr}[\exp(-H/T)] = \sum_{\alpha_0} \langle \alpha_0 | \exp(-H/T) | \alpha_0 \rangle$$

High-temp expansion:

Z =

 $\sum_{n=0}^{\infty} \frac{1}{n!T^n} \sum_{S_n} \langle \alpha_0 | (-H_n) | \alpha_{n-1} \rangle \langle \alpha_{n-1} | (-H_{n-1}) | \alpha_{n-2} \rangle \dots \langle \alpha_1 | (-H_1) | \alpha_0 \rangle$ Stochastic series expansion (SSE): Sample sum over *operator-strings* S_n of length *n* with weight above. (Sandvik 1991)

(日) (日) (日) (日) (日) (日) (日)

• Every $J > 0 \rightarrow$ minus sign

Periodicity, closed-loops and the overall sign

- Overall sign insensitive to $|\alpha\rangle \rightarrow e^{i\gamma(\alpha)}|\alpha\rangle$ no quick fix...
- Diagonal matrix elements can always be shifted to make sign positive

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

- Off-diagonal "hops" control sign
- Constrained by periodicity in τ and lattice structure

(Sign) Problems and "Solutions"...

Notorious problems:

 $H = \sum_{\langle rr' \rangle} \vec{S}_r \cdot \vec{S}_{r'}$ on Kagome, triangular lattices

d = 2 square lattice Hubbard model away from half-filling

- Some "solutions":
 - 1. Looking under the (Ising) streetlamp: Frustrated exchange couplings only involving one component of spins
 - 2. Clever change of simulation basis...?
 - Finessing the problem: Effective field theory/Hamiltonian description of low-energy physics can be numerically tractable
 - 4. Identifying symmetries that cancel -ve signs in pairs

Very difficult even if sign-free!

- Quantum and thermal fluctuations determine nature of low temperature phase & excitations
- Computational scheme needs to be ergodic within macroscopically degenerate minimally frustrated subspace
- Also needs to capture thermal fluctuations out of minimally frustrated subspace

(ロ) (同) (三) (三) (三) (○) (○)

Ideas that help: Clusters, worms, and loops.

- Cluster constructions (Wolff, Swendsen & Wang) identify and update large regions that "want to" move together (Accurately capture the physics of large correlation lengths associated with ferromagnetic criticality)
- Worm constructions (Evertz & Wiese; Prokofev & Svistunov) identify a one-dimensional cascade of moves that take system out of physical (constrained) configuration space (When worm closes on itself, system returns to physical subspace, but with large changes in configuration)

 Dual (loop) representations Bond-variables often more convenient (Hitchcock, Sorensen, Alet ...)

Issues

- Key challenge for clusters and worms: Are clusters rejected with significant probability? Do worms/clusters reflect underlying physics?
- Composition of clusters should reflect long-wavelength correlations of the system...

Algorithm needs to "know" of the physics of geometric frustration?

(ロ) (同) (三) (三) (三) (○) (○)

Example of sign-free but challenging models

- ► Ising models of quantum frustration (Moessner-Sondhi 2000) Triangular lattice Ising antiferromagnet in a transverse field $H_{\text{TFIM}} = J \sum_{\langle ij \rangle} \sigma_i^z \sigma_j^z - \Gamma \sum_i \sigma_i^x + \dots$
- Quantum cluster algorithm available in SSE representation for unfrustrated quantum Ising models (Sandvik 2003)

(日) (日) (日) (日) (日) (日) (日)

Challenge: Low but not zero temperatures

Classical frustrated Ising models: Thermal fluctuations need to be captured in efficient way Standard (Wolff-inspired) classical cluster constructions accurately reflect long-wavelength physics of ferromagnetic correlations, but not of frustration Coddington & Han 1994, Zhang and Yang 1994

Frustrated transverse field Ising models
 Quantum cluster algorithm reduces to variant of
 Swendsen-Wang clusters in Γ = 0 limit → frustrated J_{ij} again
 cause problem at low temp.

 Need to "teach" cluster algorithms structure of minimally

frustrated landscape(?)

Difficult even in classical case

- Dual worm construction (Wang,Sterck & Melko 2012)
 Uses worms to update dual variables (*a la* Hitchcock,Sorenson,Alet 2004)
- Works when T = 0 limit is dual to non-interacting dimers

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Involves rejection of significant fraction of worms

Our recent progress

- Quantum cluster construction for *frustrated* TFIM (Sounak Biswas, R. Geet, & KD, unpublished)
- Stochastic Series Expansion Quantum Monte Carlo in basis of total spin eigenstates of clusters of spins (F. Alet, KD, & S. Pujari, unpublished)
- Cluster algorithm for frustrated two-dimensional H_{Ising} with up to third neighbour interactions (KD & R. Geet, unpublished)

(日) (日) (日) (日) (日) (日) (日)

Ingredients

- Cluster constructions
- (Dual) "loop-like" (dimer) representations

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Directed worm constructions

Quantum cluster algorithm for frustrated TFIM

- ► Example: Transverse field Ising antiferromagnet on triangular lattice (also with further neighbour (*J*₂, *J*₃) couplings...)
- Interesting physics questions
 Thermodynamic signature of two-step melting of three-sublattice order

Transition from plaquette to columnar three-sublattice order

(ロ) (同) (三) (三) (三) (○) (○)

・ロン ・聞 と ・ ヨ と ・ ヨ と

Columnar vs Plaquette type orders

 $\Psi = |\Psi| e^{i\theta}$

 $\theta = 2\pi m/6$: Columnar three-sublattice order (m = 0, 1, 2...6)

 $\theta = (2m + 1)\pi/6$: Plaquette three-sublattice order (m = 0, 1, 2...6) In ordered state: θ pinned to these values

Columnar phase is ferrimagnetic $m \propto \cos(3\theta)$

In power-law phase: θ has gaussian fluctuations with no pinning

Vertices and weights

Proof of sign-free nature

Periodicity and bipartiteness implies constraints

- $N_p + N_{pm}$ must at least be even.
- $\mathcal{N}_m + \mathcal{N}_{pm} + \mathcal{N}_{lm}$ must also be even.
- $N_l + N_{lm}$ must also be even.
- If $K_{\perp} = 0$, we have $\mathcal{N}_{lm} = \mathcal{N}_{pm} = 0$. No sign problem

(日) (日) (日) (日) (日) (日) (日)

• If $K_z = 0$, we have $\mathcal{N}_l = \mathcal{N}_p = 0$. No sign problem

Illustration: Fully frustrated ladder with $K_z \neq 0$

 H_{bilayer} in d = 1 with $\mathcal{D}_z = \mathcal{D}_\perp = 1$, $\mathcal{J}_\perp = \mathcal{K}_\perp = 1$, $\mathcal{J}_z = 1 + K_z$, $\mathcal{K}_z = 1 - K_z$, as a function of rescaled temperature T/K_z with linear size (number of unit-cells) L = 64.

The inset shows the perfect agreement between QMC data (symbols) and exact diagonalization results (lines) for a system of linear size L = 6.

Can we access SU(2) symmetric frustrated bilayers?
