# Crawling towards the continuum

- **Before this year:** state of the art lattice computations of physics at finite chemical potential used lattice cutoff  $\Lambda = 4T \simeq 800$  MeV near  $T_c$ .
- Our earlier computation used  $m_\pi \simeq 230$  MeV and spatial sizes with  $LT = 2, 3, 4$  and 6. This enabled extrapolation to the thermodynamic limit, *i.e.*,  $L \rightarrow \infty$ .
- **Now:** new computations with  $\Lambda = 6T \simeq 1200$  MeV near  $T_c$ .
- $m_\pi$  remains unchanged (230 MeV), but spatial volumes are somewhat smaller ( $LT = 2, 3$  and 4). No extrapolation to  $L \rightarrow \infty$  yet.
- 20000–50000 configurations at each coupling; stochastic determination of traces with 500 random vectors on each configuration. (Gavai and SG, Phys. Rev. D 68, 2003, 034506.)

# Algorithmic issues

- For  $N_f = 2$  simulations with staggered quarks we used R-algorithm. Most runs used trajectory length of 1 MD time unit and  $\delta T = 0.01$ .
- Test case:  $m/T_c = 0.1$ ,  $6 \times 24^3$  lattice. Changed  $\delta T$  from 0.01 to 0.001. No change in bulk quantities: plaquettes, Re L, quark condensate.
- For same test case, changed trajectory length from 1 MD time unit to 3 MD time units. No change in bulk quantities, but with longer trajectories autocorrelation lengths decreased so that CPU time taken for generating decorrelated configs decreased.

# Locating the finite temperature cross over

- Cross-over coupling monitored using Polyakov Loop susceptibility:  $\chi_L$ , an operator which enters fourth-order QNS:  $(T/V)\langle O_{22} \rangle_c$ , and an operator which enters eighth-order QNS:  $(T/V)\langle O_{44} \rangle_c$ . Measures consistent with each other within the precision of this work.
- For  $m/T_c = 0.1$ , we find  $\beta_c = 5.425(5)$ . Previous results bracketed this: for  $m/T_c = 0.15$  one had  $\beta_c = 5.438(40)$  (Gottlieb et al, PRL 59, 1987, 1513) and for  $m/T_c = 0.075$  it was found that  $\beta_c = 5.41\text{--}5.43$  (Bernard et al, PR D 45, 1992, 3854).
- Transition is not first order. Computations at larger volumes are required to distinguish cross over from second order transition.

# What is a QNS?

Taylor coefficient of the pressure in  $N_f = 2$  QCD is

$$P(T, \mu_u, \mu_d) = \sum_{n_u, n_d} \frac{1}{n_u! n_d!} \chi_{n_u, n_d}(T) \mu_u^{n_u} \mu_d^{n_d},$$

and, since the two quark flavours are degenerate,  $\chi_{n_u, n_d} = \chi_{n_d, n_u}$ .

Diagonal QNS have either  $n_u = 0$  or  $n_d = 0$ .

In two flavour QCD trade  $\mu_{u,d}$  for  $\mu_{B,Q}$ . Then

$$\chi_B = \frac{2}{9} (\chi_{20} + \chi_{11}) = 2\chi_{BQ}$$

$$\chi_Q = \frac{1}{9} (5\chi_{20} - 4\chi_{11}).$$

Transforming to  $\mu_{B,I_3}$ , one has

$$\chi_{BI_3} = 0, \quad \chi_{I_3} = \frac{1}{2} (\chi_{20} - \chi_{11}).$$

## Off-diagonal QNS

Sees only  $\langle O_{11} \rangle$ . No evidence for lattice spacing effects.

# Diagonal QNS

Sees  $\langle O_{11} \rangle$  and  $\langle O_2 \rangle$ . Second expectation value is cutoff dependent. Also, has a cross over. We look at its susceptibility  $\langle O_{22} \rangle_c$  to identify  $T_c$ .

# “Susceptibility” of QNS: $\langle O_{22} \rangle_c$ — 4th order QNS

Peak at the same coupling as peak of  $\chi_L$ . Within the 1% precision of  $T/T_c$ , the two quantities peak at the same coupling. See Gavai and Gupta, PR D72 (2005) 054006.

# Diagonal fourth-order QNS

Non-zero for  $T > T_c$ . Has contribution from  $\langle O_4 \rangle$ , which has non-vanishing value for the ideal gas.

# The operator $O_4$

Rapid cross over from a small value in the hadronic phase to a non-vanishing value for the ideal gas.

# “Susceptibility” of $O_4$ : $\langle O_{44} \rangle_c$ — 8th order QNS

This quantity peaks at the same coupling as  $\chi_L$  and  $\langle O_{22} \rangle_c$ . Within the precision of our measurement there is no dependence of the cross over coupling on these observables.

# The operator $O_6$ — 6th order QNS

The operator expectation value  $\langle O_6 \rangle$  has structure below  $T_c$  and hence its “susceptibility” cannot be used to probe the cross over coupling. Similar observation for  $\langle O_8 \rangle$ .

- 1 The finite temperature transition
- 2 Quark Number Susceptibilities
- 3 Linkage**
- 4 The Critical End Point
- 5 Series sums and Padé resummations
- 6 Summary

# Linkage between quantum numbers

- Linkage between quantum numbers  $F$  and  $G$  is

$$C_{(FG)|F} = \frac{\chi_{FG}}{\chi_F} = C_{(GF)|F}.$$

Measures amount of  $G$  excited per unit fluctuation in  $F$ . The quantities  $C_{(FG)|F}$  and  $C_{(FG)|G}$  not necessarily equal.

- $C_{(ud)|u} = -2/3$  at low temperature, since the pion is the lightest excitation, and at high temperature it vanishes. For  $N_f = 2$  one has  $C_{(ud)|u} = C_{(ud)|d}$ .
- $C_{(BQ)|Q} = 0$  at low temperatures (pion is the lightest particle) and  $1/5$  at high temperature.
- $C_{(BQ)|B} = 1/2$  at all temperatures by definition.

# Results

Quick cross over from hadron gas behaviour to quark gas behaviour.  
 Rounding seen close to  $T_c$ . Finite-size effects need to be investigated:  
 $LT = 4$ . Earlier computation with  $N_t = 4$  saw less rounding with  $LT = 6$ .

# Finite size effects

- At critical point correlation length becomes infinite, appropriate susceptibilities diverge and free energy becomes singular ... in the infinite volume limit (van Hove's theorem).
- No numerical computation ever performed on infinite volumes.
- Deduce the existence of a critical point through extrapolations: finite size scaling (FSS) well developed for direct simulations.
- Example: peak of susceptibility scales as power of volume. Smaller effect: position of peak shifts from its infinite volume position by a different power of volume—

$$\chi_{\max}(L) \propto L^p, \quad T_c(L) = T_c - a/L^q, \quad (p, q > 0).$$

- FSS not well developed for series expansions; some aspects are known.

# Series expansions

For a divergent quantity:  $\chi(T, \mu_B) = \sum_n c_n(T) \mu_B^n$ , the leading finite volume effects in the series coefficients.

$$N_t = 4$$

At fixed  $T/T_c \simeq 0.95$ . Circles: ratio of order 0 and 2; boxes: ratio of order 2 and 4. Gavai and SG, Phys. Rev. D 71, 2005, 114014.

# $N_t = 6$ : Radius of convergence

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

# $N_t = 6$ : Radius of convergence

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

# $N_t = 6$ : Radius of convergence

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

# Radius of convergence

Lattice spacing dependence quantifies possible systematic errors.

# $N_t = 6$ : Finite size scaling

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

# $N_t = 6$ : Finite size scaling

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

# $N_t = 6$ : Finite size scaling

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

# Critical end point

- Multiple criteria agree:
  - Stability of radius of convergence with order and estimator
  - Pinching of the radius of convergence with  $T$ .
  - Smallest  $T$  where all the coefficients are positive.
  - Finite size effects roughly correct; more planned for the future.
- This gives

$$\frac{T^E}{T_c} = 0.94 \pm 0.01 \quad \text{and} \quad \frac{\mu_B^E}{T^E} = 1.8 \pm 0.1$$

with  $Nf = 2$  when  $m_\pi/m_\rho \simeq 0.3$  at a finite volume with  $LT = 4$  and lattice cutoff of  $a = 1/6 T^E$ .

- For a lattice cutoff of  $a = 1/4 T^E$  at the same renormalized quark mass and on the same volume we had found a similar value for  $T^E/T_c$  and  $\mu_B^E/T^E = 1.3 \pm 0.3$ . Extrapolation to  $L \rightarrow \infty$  reduced this to  $1.1 \pm 0.1$ .

- 6 Summary

# Fluctuations of Baryon number

Suggestion by Stephanov, Rajagopal, Shuryak; Asakawa, Heinz, Muller; Jeon, Koch

$$P(\Delta B) = \exp \left( - \frac{(\Delta B)^2}{2VT\chi_B} \right).$$

Extrapolate  $\chi_B$  to finite chemical potential: peak at  $T_c$ ?

# Sum the series

Summing the series never shows critical behaviour: sum is a polynomial and smoothly behaved. The sum peaks at  $T_c$ : incorrect (see SG, SEWM 2006).

# Critical fluctuations

Use Padé approximants for the extrapolations: divergence at the critical end point (see Lombardo, Mumbai 2005). Error propagation requires care: see arXiv:0806.2233 [hep-lat].

# Outline

- 1 The finite temperature transition
- 2 Quark Number Susceptibilities
- 3 Linkage
- 4 The Critical End Point
- 5 Series sums and Padé resummations
- 6 Summary**

# Summary 1: finite temperature

- 1 Simulations of  $N_f = 2$  QCD (staggered quarks, Wilson action) with renormalized quark mass  $m_\pi \simeq 230$  MeV with  $1/a \simeq 1200$  MeV and  $LT = 2, 3$  and  $4$ .
- 2 Finite temperature cross over located at  $\beta_c = 5.425(5)$ , consistent with previous computations at neighbouring masses. Consistent measurements obtained with  $\chi_L$ ,  $(T/V)\langle O_{22} \rangle_c$  and  $(T/V)\langle O_{44} \rangle_c$  within precision of this computation.
- 3 Cutoff artifacts seen in many QNS. Surprisingly, measurements are more well-behaved at smaller lattice spacing (see  $\chi_{60}$  and  $\chi_{80}$ , for example).

## Summary 2: finite chemical potential

- 1 Very stable estimate of the critical end point: three criteria agree.

$$\frac{T^E}{T_c} = 0.94 \pm 0.01 \quad \text{and} \quad \frac{\mu_B^E}{T^E} = 1.8 \pm 0.1$$

with lattice cutoff of  $a = 1/6 T^E \simeq 1100$  MeV, compared to  $\mu_B^E/T^E = 1.3 \pm 0.3$  at  $a = 1/4 T^E \simeq 750$  MeV on the same spatial volume.

- 2 Series extrapolation needs resummation: Padé approximants are one possible resummation.
- 3 Linkage between  $u$  and  $d$  quantum numbers disappears at  $T \simeq T_c$  when  $\mu_B = 0$ . How abrupt? Requires finite size scaling.
