# Crawling towards the continuum

- $\mu_B \neq 0$  through Taylor expansions of thermodynamic quantities.
- **Before this year:** state of the art lattice computations of physics for  $\mu_B \neq 0$  used lattice cutoff  $\Lambda = 4T \simeq 800$  MeV near  $T_c$ .
- Our earlier computation used  $m_\pi \simeq 230$  MeV and spatial sizes with  $LT = 2, 3, 4$  and  $6$ . This enabled extrapolation to the thermodynamic limit, *i.e.*,  $L \rightarrow \infty$ .
- **Now:** new computations with  $\Lambda = 6T \simeq 1200$  MeV near  $T_c$  (Gavai and SG, arXiv:0806.2233 [hep-lat]).
- $m_\pi$  remains unchanged (230 MeV), but spatial volumes are somewhat smaller ( $LT = 2, 3$  and  $4$ ). No extrapolation to  $L \rightarrow \infty$  yet.
- 20000–50000 configurations ( $\geq 100$  independent) at each coupling; stochastic determination of traces with 500 random vectors on each configuration. (Gavai and SG, Phys. Rev. D 68, 2003, 034506.)

# What is a QNS?

Taylor coefficient of the pressure in  $N_f = 2$  QCD is

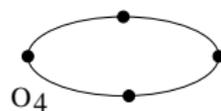

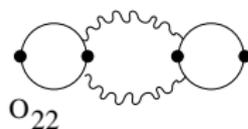

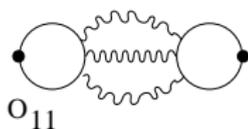

$$P(T, \mu_u, \mu_d) = \sum_{n_u, n_d} \frac{1}{n_u! n_d!} \chi_{n_u, n_d}(T) \mu_u^{n_u} \mu_d^{n_d},$$

and, since the two quark flavours are degenerate,  $\chi_{n_u, n_d} = \chi_{n_d, n_u}$ . Trade  $\mu_{u,d}$  for  $\mu_{B,Q}$ . Then

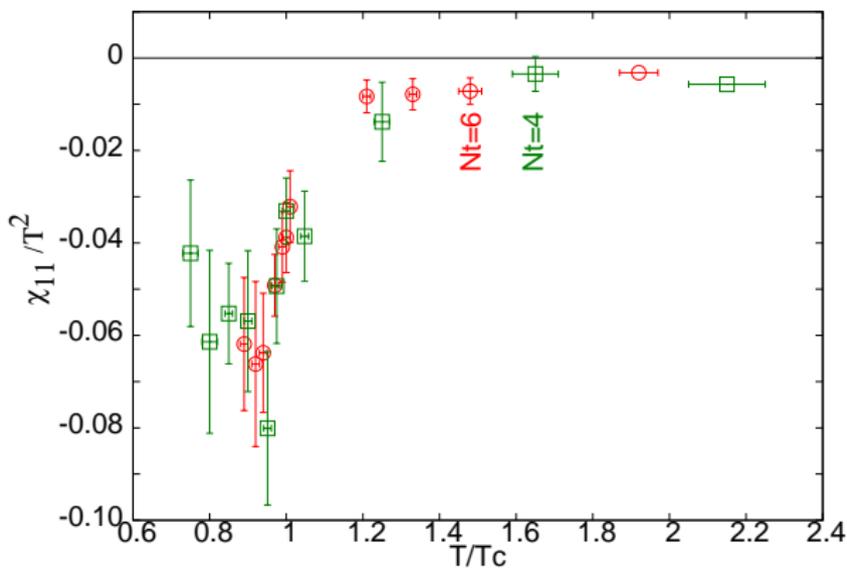

$$\chi_B = \frac{2}{9} (\chi_{20} + \chi_{11}) = 2\chi_{BQ} \quad \chi_Q = \frac{1}{9} (5\chi_{20} - 4\chi_{11}).$$

Transforming to  $\mu_{B,I_3}$ , one has

$$\chi_{BI_3} = 0, \quad \chi_{I_3} = \frac{1}{2} (\chi_{20} - \chi_{11}).$$

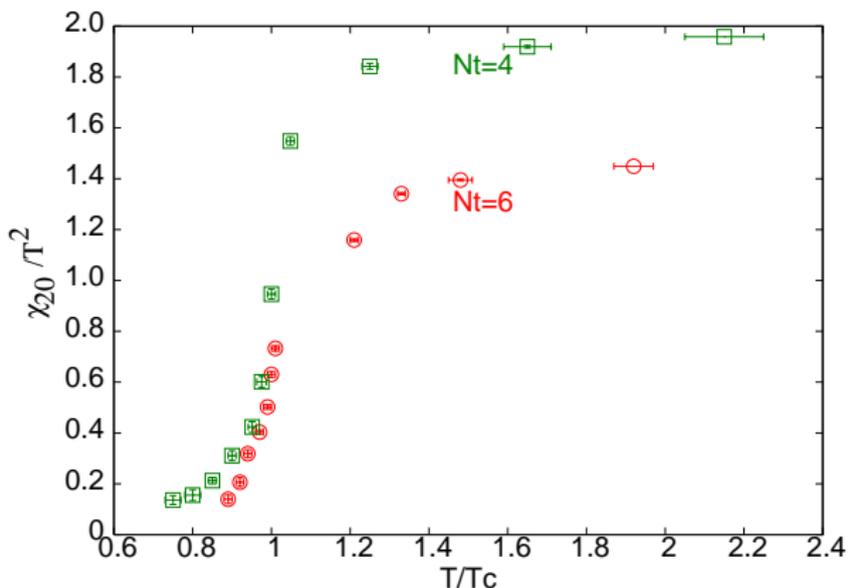

## Off-diagonal QNS

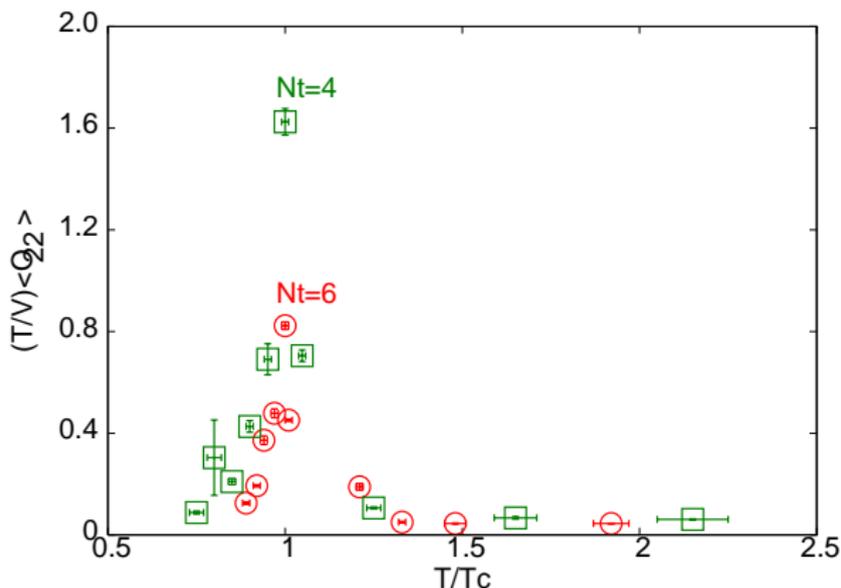

Sees only  $\langle O_{11} \rangle$ . No evidence for lattice spacing effects.

## Diagonal QNS

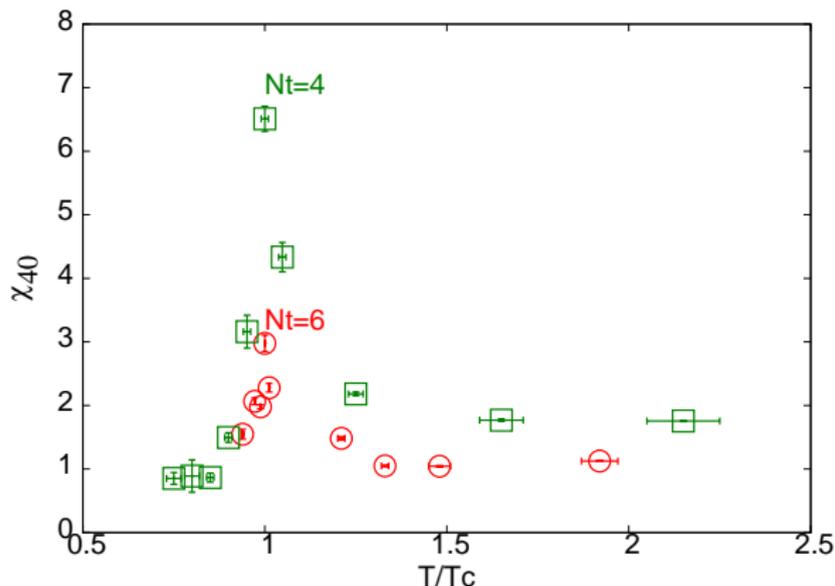

Sees  $\langle O_{11} \rangle$  and  $\langle O_2 \rangle$ . Second expectation value is cutoff dependent. Also, has a cross over. We look at its susceptibility  $\langle O_{22} \rangle_c$  to identify  $T_c$ .

# “Susceptibility” of QNS: $\langle O_{22} \rangle_c$ — 4th order QNS

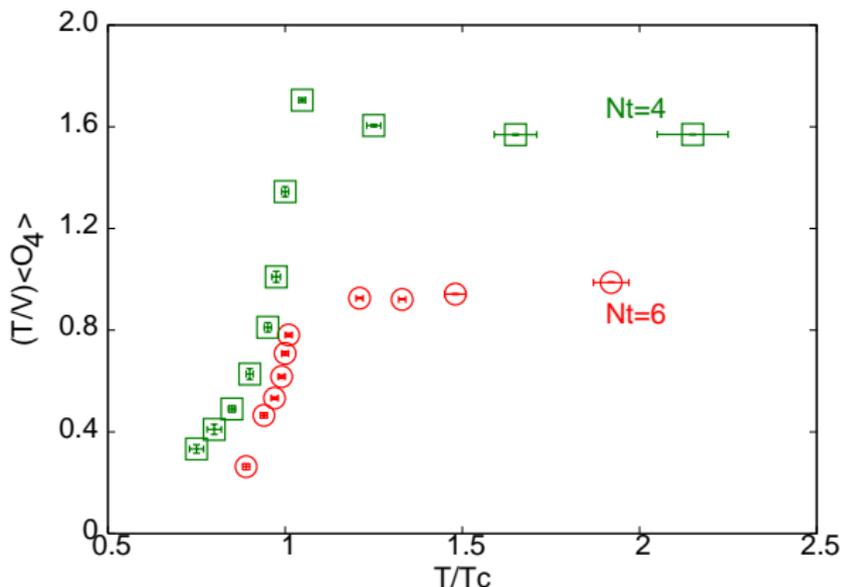

Peak at the same coupling as peak of  $\chi_L$ . Within the 1% precision of  $T/T_c$ , the two quantities peak at the same coupling. See Gavai and Gupta, PR D72 (2005) 054006.

# Diagonal fourth-order QNS

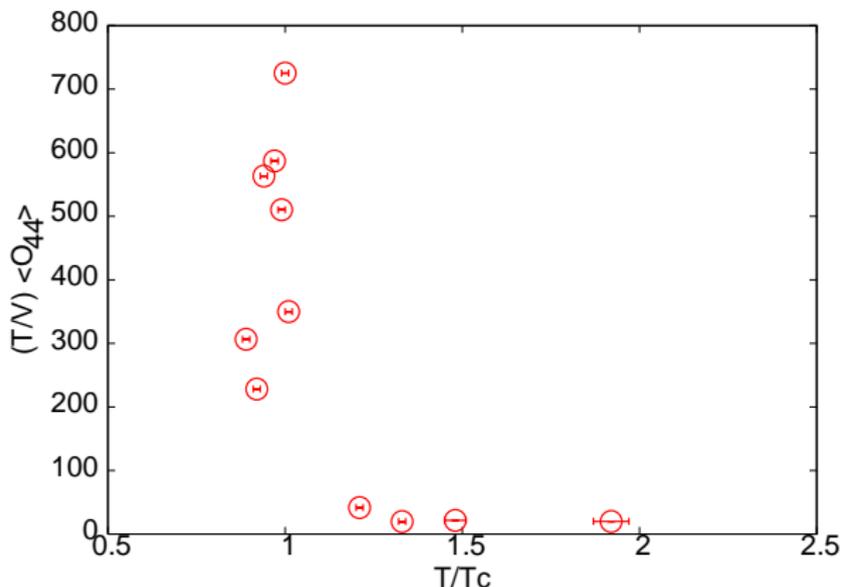

Non-zero for  $T > T_c$ . Has contribution from  $\langle O_4 \rangle$ , which has non-vanishing value for the ideal gas.

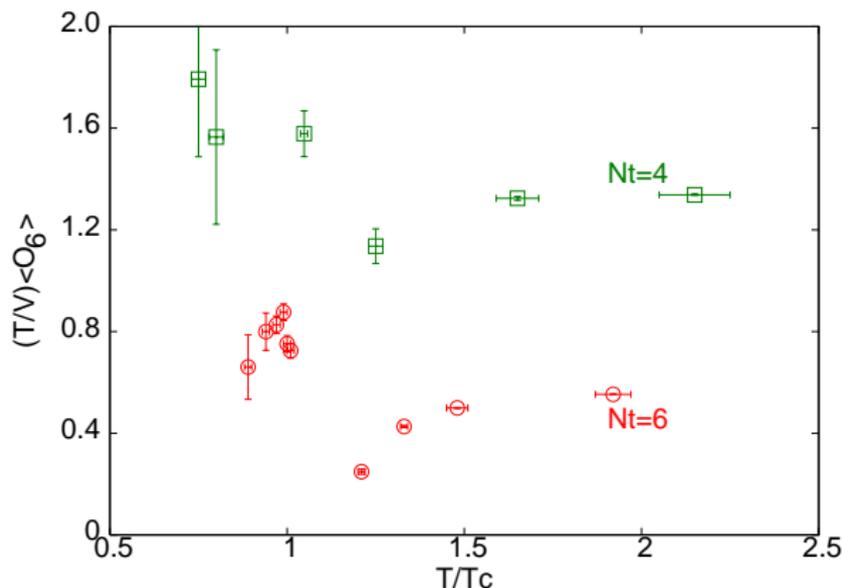

The operator  $O_4$ 

Rapid cross over from a small value in the hadronic phase to a non-vanishing value for the ideal gas.

# “Susceptibility” of $O_4$ : $\langle O_{44} \rangle_c$ — 8th order QNS

This quantity peaks at the same coupling as  $\chi_L$  and  $\langle O_{22} \rangle_c$ . Within the precision of our measurement there is no dependence of the cross over coupling on these observables.

The operator  $O_6$ — 6th order QNS

The operator expectation value  $\langle O_6 \rangle$  has structure below  $T_c$  and hence its “susceptibility” cannot be used to probe the cross over coupling. Similar observation for  $\langle O_8 \rangle$ .

# Finite size effects

- At critical point correlation length becomes infinite, appropriate susceptibilities diverge and free energy becomes singular ... in the infinite volume limit (van Hove's theorem).
- No numerical computation ever performed on infinite volumes.
- Deduce the existence of a critical point through extrapolations: finite size scaling (FSS) well developed for direct simulations.
- Example: peak of susceptibility scales as power of volume. Smaller effect: position of peak shifts from its infinite volume position by a different power of volume—

$$\chi_{max}(L) \propto L^p, \quad T_c(L) = T_c - a/L^q, \quad (p, q > 0).$$

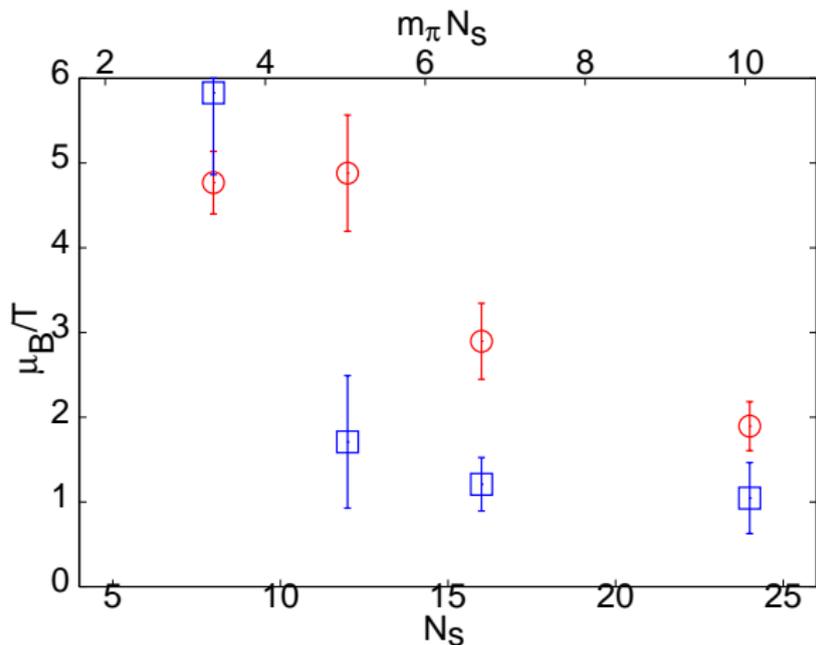

- FSS not well developed for series expansions; some aspects are known.

## Series expansions

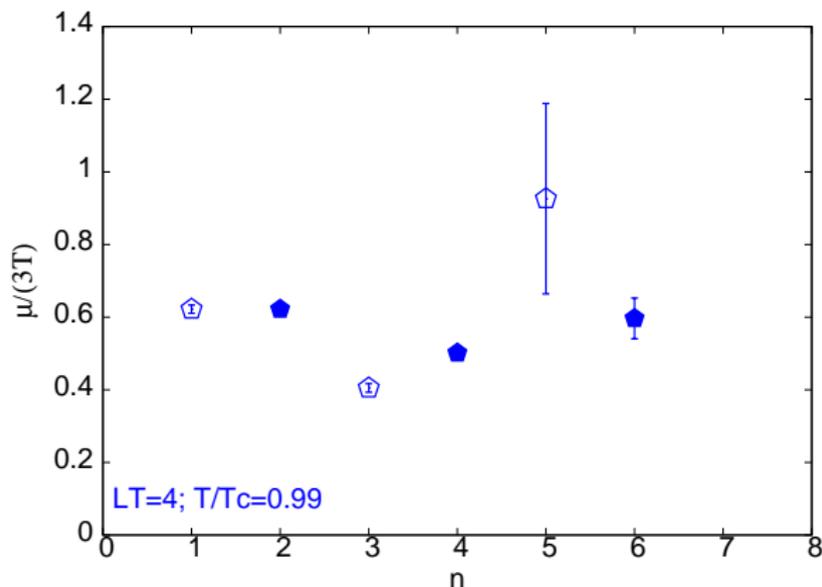

For the divergent quantity:  $\chi_B(T, \mu_B) = \sum_n \chi^{(n)}(T) \mu_B^n$ , the leading finite volume effects in the series coefficients.

$$N_t = 4$$

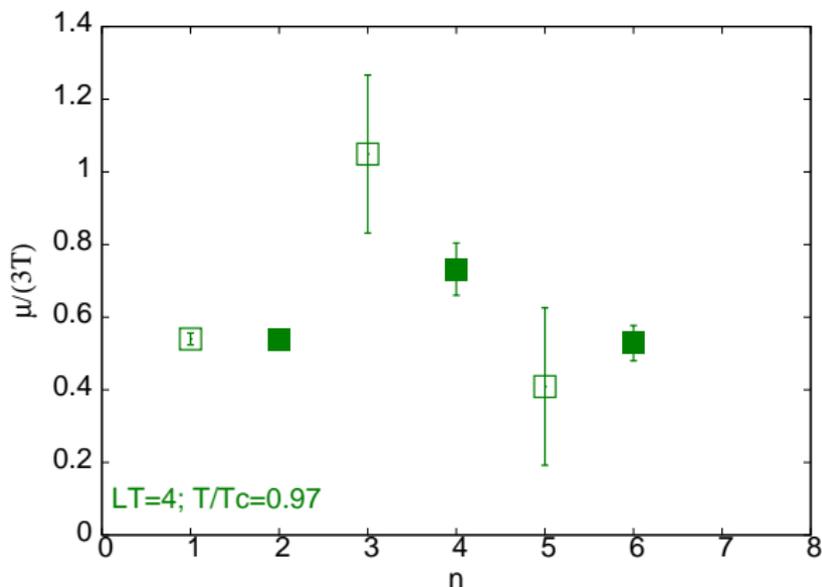

At fixed  $T/T_c \simeq 0.95$ . Circles: ratio of order 0 and 2; boxes: ratio of order 2 and 4. Gavai and SG, Phys. Rev. D 71, 2005, 114014.

# $N_t = 6$ : Radius of convergence

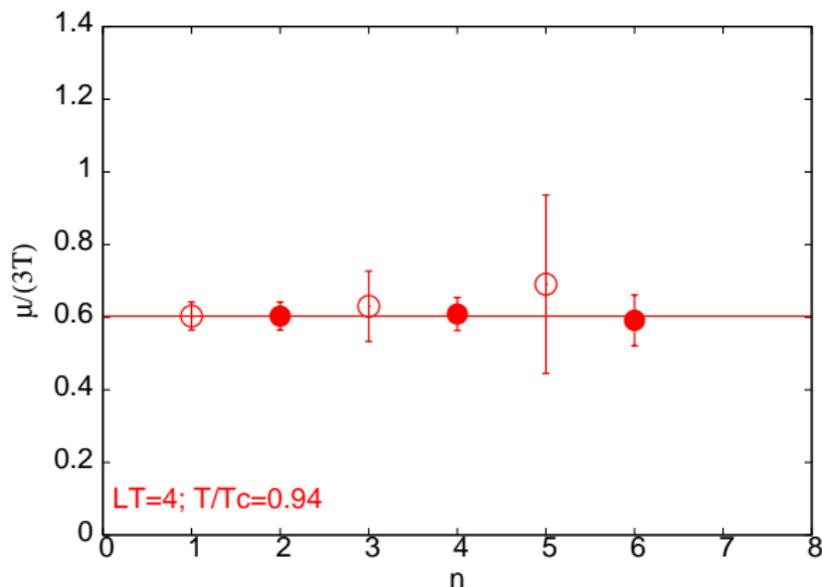

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

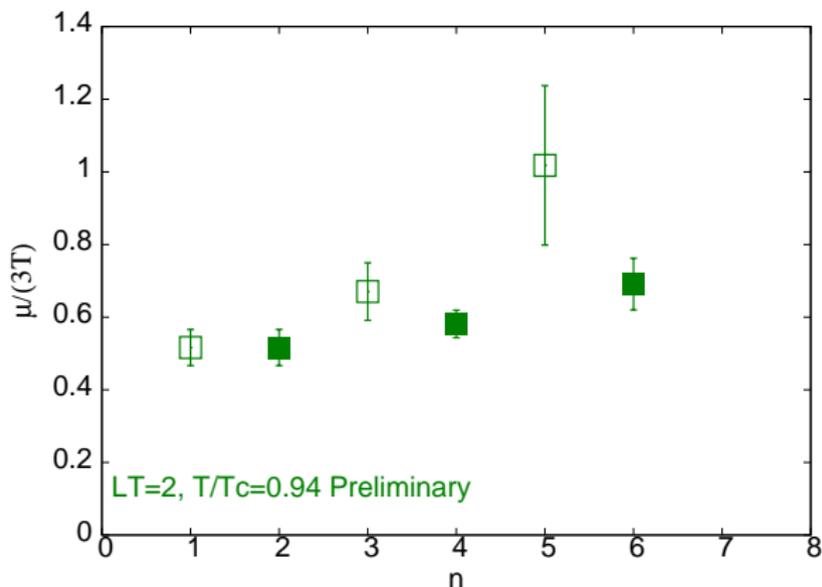

# $N_t = 6$ : Radius of convergence

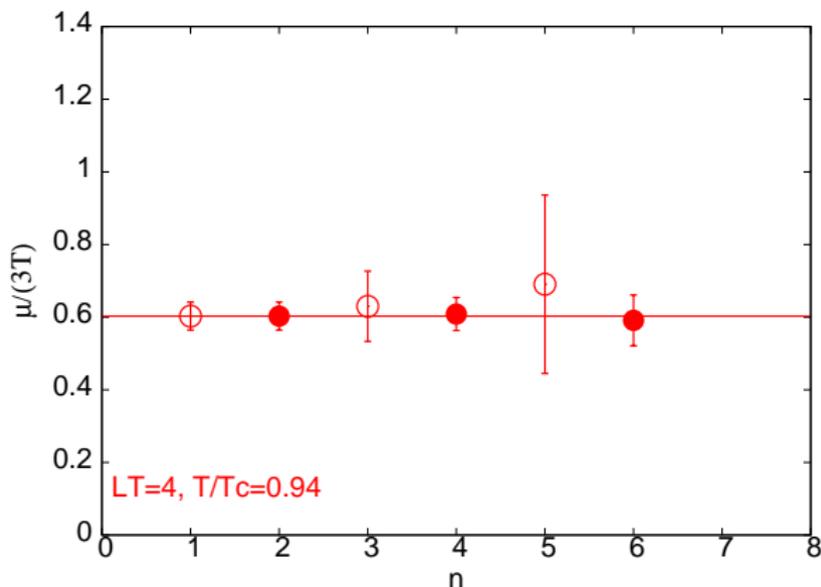

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

$N_t = 6$ : Radius of convergence

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

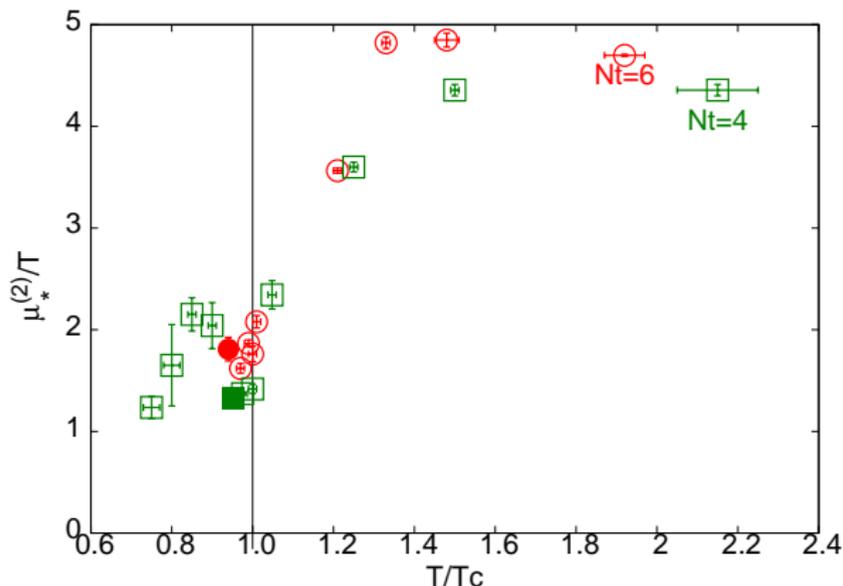

$N_t = 6$ : Finite size scaling

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

$N_t = 6$ : Finite size scaling

Filled symbols:  $(\chi^{(0)}/\chi^{(n)})^{1/n}$ . Open symbols:  $\sqrt{\chi^{(n-1)}/\chi^{(n+1)}}$ .

# “Kurtosis” and radius of convergence

Plot of  $\sqrt{12\chi^{(2)}/\chi^{(4)}}$ . Lattice spacing dependence quantifies possible systematic errors. Related to Kurtosis: experimental measurement possible.

# Critical end point

- Multiple criteria agree:
  - Small window in  $T$  where all the coefficients are positive.
  - Stability of radius of convergence with order and estimator
  - Finite size effects follow correct trend; more planned for the future.
  - Pinching of the radius of convergence with  $T$ : (experimental measurement of Kurtosis?)
- This gives

$$\frac{T^E}{T_c} = 0.94 \pm 0.01 \quad \text{and} \quad \frac{\mu_B^E}{T^E} = 1.8 \pm 0.1$$

with  $Nf = 2$  when  $m_\pi/m_\rho \simeq 0.3$  at a finite volume with  $LT = 4$  and lattice cutoff of  $a = 1/6 T^E$ .

- For a lattice cutoff of  $a = 1/4 T^E$  at the same renormalized quark mass and on the same volume we had found a similar value for  $T^E/T_c$  and  $\mu_B^E/T^E = 1.3 \pm 0.3$ . Extrapolation to  $L \rightarrow \infty$  reduced this to  $1.1 \pm 0.1$ .

# Fluctuations of Baryon number

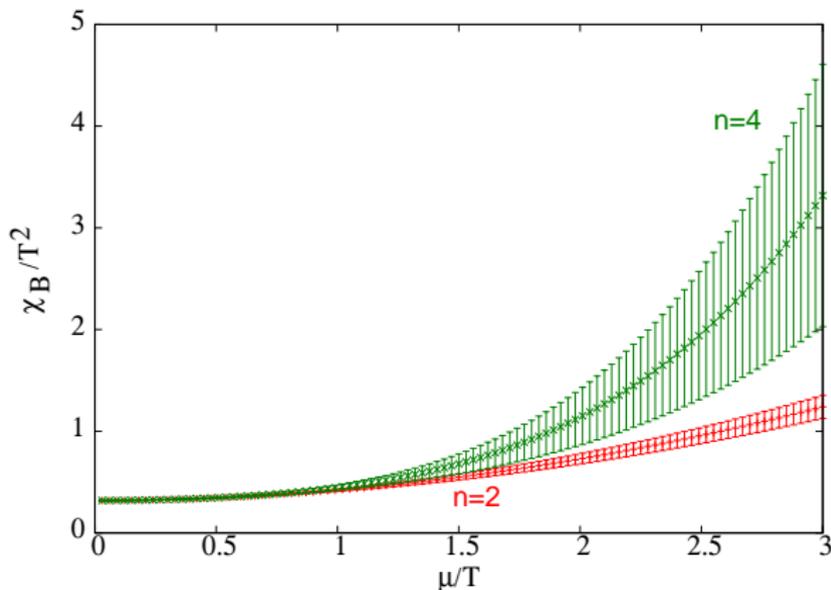

Suggestion by Stephanov, Rajagopal, Shuryak; Asakawa, Heinz, Muller; Jeon, Koch

$$P(\Delta B) = \exp\left(-\frac{(\Delta B)^2}{2VT\chi_B}\right).$$

Extrapolate  $\chi_B$  to finite chemical potential: peak at  $T_c$ ?

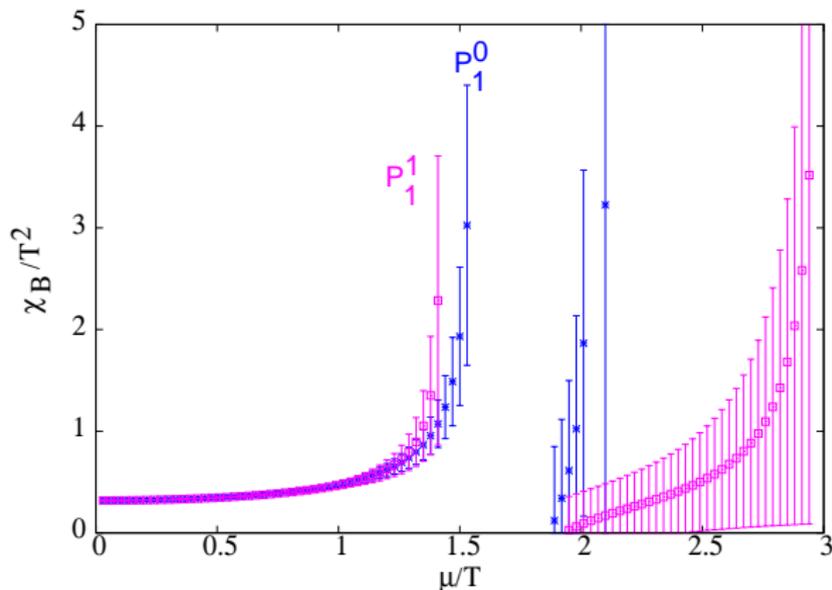

## Sum the series

Summing the series never shows critical behaviour: sum is a polynomial and smoothly behaved. The sum peaks at  $T_c$ : incorrect (see SG, SEWM 2006).

# Critical fluctuations

Use Padé approximants for the extrapolations: divergence only at the critical end point. Error propagation requires care: see arXiv:0806.2233 [hep-lat].

# Outline

- 1 Quark Number Susceptibilities
- 2 The Critical End Point
- 3 Series sums and Padé resummations

# Experimental measurement of critical index

Near the critical point

$$\chi^{(2)} \propto |\mu - \mu_B^E|^{-\gamma}, \quad \chi^{(4)} \propto |\mu - \mu_B^E|^{-\gamma-2} \quad (\gamma > 0).$$

The Kurtosis diverges:

$$K = -1 + \frac{\chi^{(4)}}{3[\chi^{(2)}]^2} \propto |\mu - \mu_c|^{\gamma-2};$$

(recall that  $P = P_0 + p|\mu - \mu_c|^{-\gamma+2}$  is non-analytic but non-divergent).

Along freezeout trajectory in an energy scan, the Kurtosis is non-monotonic. Should be visible in experiment. Look for non-Gaussian (E-to-E) fluctuations. Big question: what can hide non-Gaussian fluctuations?

Exciting possibility: **can one measure a critical index in experiments?**
