Theoretical underpinning

Does QCD describe this matter? Is there a new nonperturbative test of QCD?

Predictions from QCD

- Lagrangian has free parameters: cutoff a, quark masses $m_u \simeq m_d \ll \Lambda_{QCD}$, $m_s \simeq \Lambda_{QCD}$, $\cdots$
- Compute enough quantities from QCD: $m_\pi(a, m_{ud}, m_s, \cdots)$, $m_K(a, m_{ud}, m_s, \cdots)$, $f_K(a, m_{ud}, m_s, \cdots)$, $f_\pi(a, m_{ud}, m_s, \cdots)$, $m_\rho(a, m_{ud}, m_s, \cdots)$, $m_p(a, m_{ud}, m_s, \cdots)$, $T_c(a, m_{ud}, m_s, \cdots)$, $T_E(a, m_{ud}, m_s, \cdots)$, $\mu_E(a, m_{ud}, m_s, \cdots)$
- Fix the free parameters using some of the predictions. Then the remaining are scale-free predictions.

- Fix the free parameters using some of the predictions. Then the remaining are scale-free predictions.
- Take the cutoff to infinity. Difficult on the lattice; many technical innovations on how to get stable predictions with small dependence on a.

Outline

Fluctuations of conserved quantities

Observations

In a single heavy-ion collision, each conserved quantity (B, Q, S) is exactly constant when the full fireball is observed. In a small part of the fireball they fluctuate: from part to part and event to event.

Fluctuations of conserved quantities

Observations

In a single heavy-ion collision, each conserved quantity (B, Q, S) is exactly constant when the full fireball is observed. In a small part of the fireball they fluctuate: from part to part and event to event.

Thermodynamics

If $\xi^3 \ll V_{obs} \ll V_{fireball}$, then fluctuations can be explained in the grand canonical ensemble: energy and B, Q, S allowed to fluctuate in one part by exchange with rest of fireball (diffusion: transport).

Fluctuations of conserved quantities

Observations

In a single heavy-ion collision, each conserved quantity (B, Q, S) is exactly constant when the full fireball is observed. In a small part of the fireball they fluctuate: from part to part and event to event.

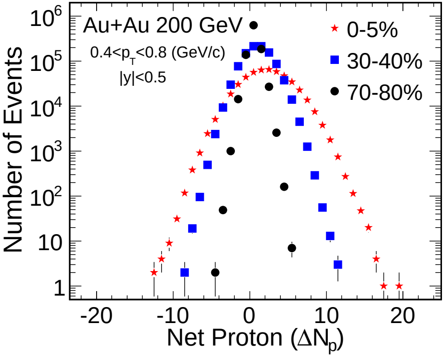
Thermodynamics

If $\xi^3 \ll V_{obs} \ll V_{fireball}$, then fluctuations can be explained in the grand canonical ensemble: energy and B, Q, S allowed to fluctuate in one part by exchange with rest of fireball (diffusion: transport).

Comparison

Is the observed volume small compared to the volume of the fireball? Are observations in agreement with QCD thermodynamics?

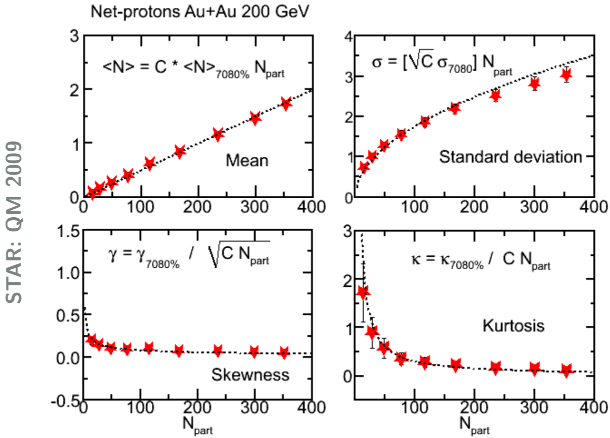
Event-to-event fluctuations



STAR arxiv:1004.4959

Central rapidity slice taken. p_T of 400–800 MeV. Important to check dependence on impact parameter. Protons observed: isospin fluctuations small.

Shape of distribution



Shape of distribution captured in cumulants $[B^n]$. Cumulants change with volume (proxy: N_{part}), and tends to Gaussian.

QCD predictions at finite μ_B

Make a MacLaurin expansion of the (dimensionless) pressure:

$$\frac{1}{T^4}P(T,\mu) = \sum_{n=0}^{\infty} T^{n-4}\chi_B^{(n)}(T,0)\frac{(\mu/T)^n}{n!},$$

measure each NLS at $\mu = 0$, sum series expansion to find NLS at any μ. Shape variables: $[B^n] = (VT^3)T^{n-4}\chi_B^{(n)}(t,\mu)$. Ratios of cumulants are state variables:

$$m_1 : \quad \frac{[B^3]}{[B^4]} = \frac{T\chi_B^{(3)}}{\chi_B^{(2)}} = S\sigma$$

$$m_2 : \quad \frac{[B^4]}{[B^2]} = \frac{T\chi_B^{(4)}}{\chi_B^{(2)}} = \kappa\sigma^2$$

$$m_3 : \quad \frac{[B^4]}{[B^3]} = \frac{T\chi_B^{(4)}}{\chi_B^{(3)}} = \frac{\kappa\sigma}{S}$$

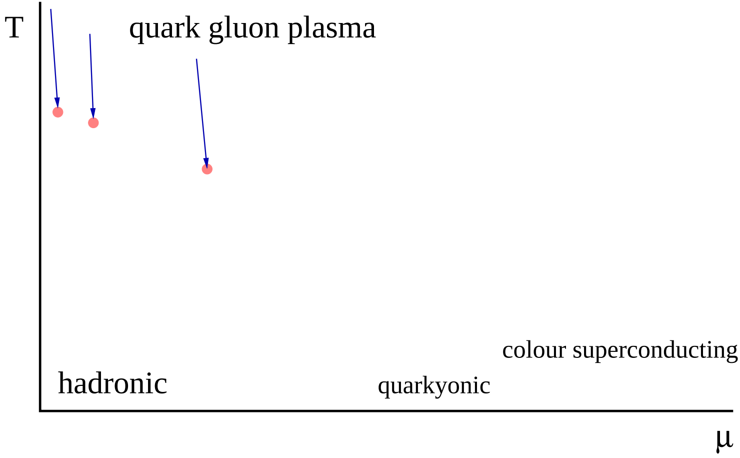
The freezeout curve



Hadron gas models: Hagedorn, Braun-Munzinger, Stachel, Cleymans, Redlich, Becattini

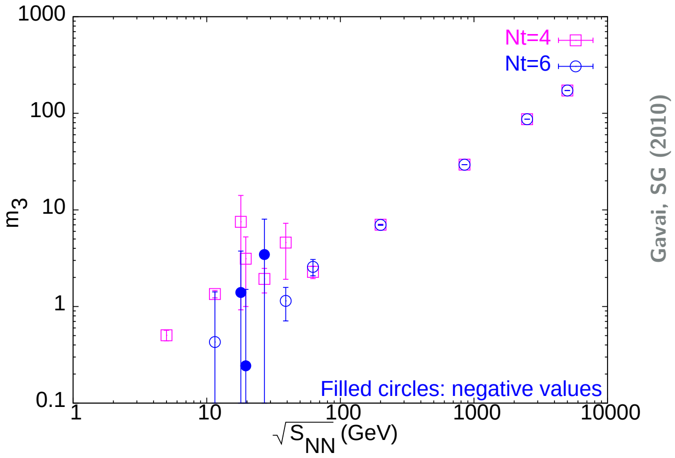
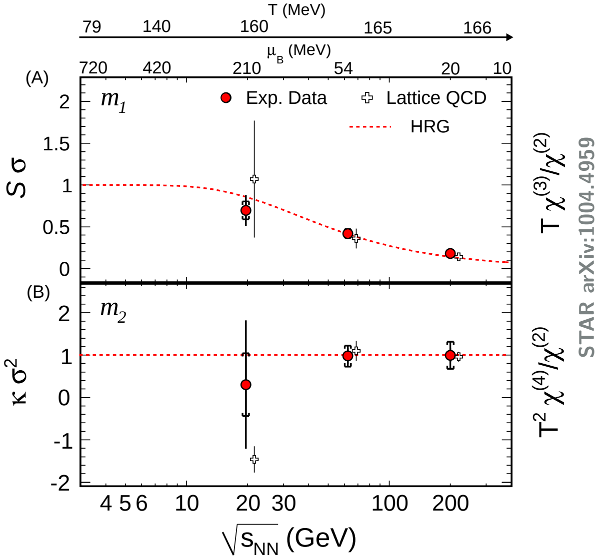
Predictions along the freezeout curve



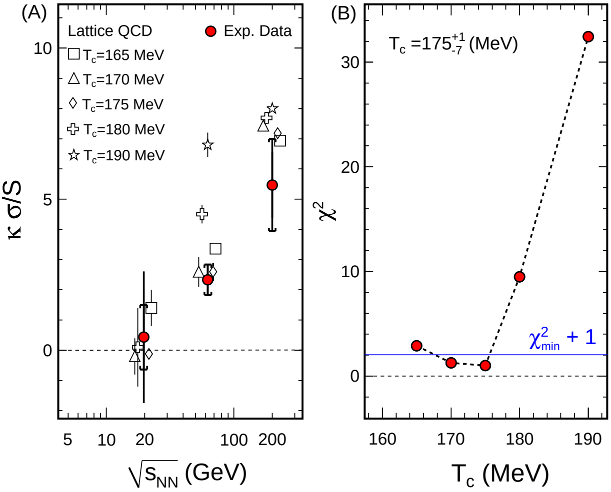
Lattice predictions along the freezeout curve of HRG models using $T_c = 170$ MeV.

Outline

Checking the match



Tuning lattice scale to match data



Science, 332 (2011) 1525

Conclusions

Thermalization

1 parameter tuning makes thermodynamic predictions agree with data for 2 ratios at 3 energies. Indicates thermalization of the fireball at freezeout.

T_c

Comparison of lattice and data along the freezeout curve gives

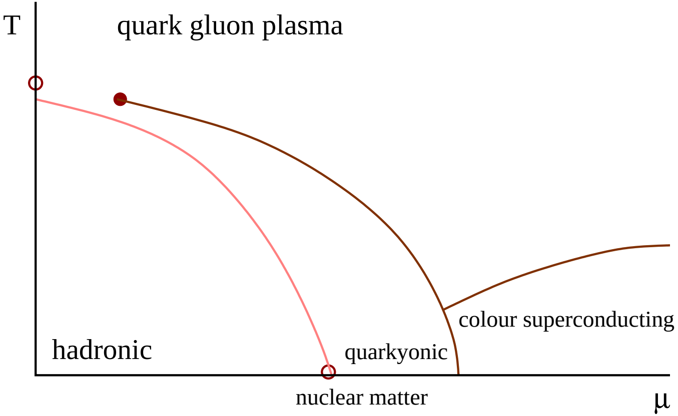
$$T_c = 175^{+1}_{-7}\ \mathrm{MeV},$$

in agreement with other scale settings on the lattice. Indicates that non-perturbative phenomena in single hadron physics and strong interaction thermodynamics are mutually consistent through QCD.

Systematics

1. How important are isospin fluctuations?
   STAR 2010, Kitazawa and Asakawa 2011
2. Are volume fluctuations important?
   STAR 2010
3. How accurately is the freezeout curve known?
4. Do chemistry fluctuations freeze out at the same time mean chemistry?
5. How important are finite lattice spacing artifacts?
   Gavai and SG 2010
6. How good is the series expansion in μ?
   York and Moore 2011
7. How good is the resummation of the series?
8. How sensitive are the results to m_{ud} and m_s?
   Gavai and SG 2008

Search for the critical point



Near a critical point system departs from equilibrium. If the critical point lies near the freezeout curve, then (1) Gaussian statistics will fail and (2) QCD predictions will not agree with data.
